## The GE Family of Molded Case Circuit Breakers

From 10-1200 Amperes

## Application Flexibility

In switchboards, motor control centers and lighting, power and customized control panelboards, General Electric molded case circuit breakers are used to provide reliable circuit protection. Molded case circuit breakers in individual enclosures are also used in numerous applications.

## Minimum Downtime

Downtime is reduced and fuse replacement is eliminated with circuit breakers. In case of overload or short circuit, the breaker trips, opening the circuit and protecting the conductors. When normal conditions are restored, the breaker can be closed ("ON") again.

## Trip-Free Mechanism

The breaker's trip-free mechanism opens the breaker contacts under overload or short circuit conditions, even with the breaker handle held in the ON position.

## Eliminates Single-Phasing

Circuit breakers eliminate single-phasing. When an overload or short circuit occurs on any one conductor, a common trip bar simultaneously disconnects all three conductors of a three-phase circuit.

## Easy System Upgrading

With General Electric circuit breakers, the circuit can be uprated, even after the breaker has been installed.
Interchangeable trips provide a wide range of ratings within the same frame size.

## Accessory Functions

Application flexibility of molded case circuit breakers is enhanced by a breaker accessory line. Remote closing or opening, undervoltage protection, indication of "tripped" condition at a remote location, electrical or mechanical interlocking, automatic reclosing, and primary or sequential operation are some of the functions practical with accessories.

## Space Savings

Space savings can be an important factor in selecting General Electric molded case circuit breakers as equipment components. Higher rated breakers in particular, offer major space economies over fused switches.

## Interrupting Ability

Interrupting ratings of General Electric molded case circuit breakers are based on actual short circuit tests. Breakers are rated for RMS symmetrical ac amperes and for maximum dc amperes.

## Standards and Specifications

General Electric molded case circuit breakers meet standards established by Underwriters' Laboratories, National Electric Manufacturers Association, Federal Specifications, Institute of Electronic Engineers, National Electric Code and General Electric Company's own high quality standards.

## Rugged, Dependable Construction

## Circuit Breaker Frame

- Molded case is molded from high-mechanical and high-dielectric strength engineered plastic.
- Trip indication is shown by handle position midway between ON and OFF. To reset the trip mechanism, move the handle to extreme OFF, then to ON position.
- Quick-make, quick-break, trip-free mechanism minimizes arcing during breaker operation. Contacts cannot be "teased" into position. Trip-free mechanism is independent of manual handle control. The breaker trips under short circuit or overload, even though the operating handle is held in ON position.
- Verifier "Twist-to-Trip" and "Push-to-Trip" mechanically simulates over-current tripping through actuation of linkages not operated by the ON-OFF handle. Experience has shown that thermal magnetic circuit breakers in industrial applications better maintain their original protective characteristics when regularly exercised.
- Common-trip bar assures instant disconnect of all conductors when an overload or short circuit occurs on any one conductor in the circuit, or an accessory trip device operates.
- Silver alloy contacts combine the conductive properties of silver with other elements for clean, positive electrical contacting. Pitting and burning are minimized for longer contact life.
- Arc chutes of heat-absorbing, insulating material and metal grid plates quickly "extinguish" arcs.
- UL listed lugs for copper or aluminum cable, at full frame rating. Easy access and simple, straight-in wiring.

## Thermal Magnetic Trip System

- Front-adjustable magnetic trip provides instantaneous trip in event of short circuit. Any current surge above the trip setting produces a magnetic field which instantly actuates the trip mechanism and opens the circuit.
- Thermal trip provides protection against sustained overloads. A bi-metallic element reacts time-wise in inverse proportion to the current. If a circuit is overloaded, heat resulting from excessive current flow causes the bi-metal to bend, actuating the trip mechanism to open the circuit.
- Interchangeable trip units (for frames over 150 ampere rating) simplify stocking and reduce inventory requirements. Field interchangeability assures maximum flexibility.

## Electronic Trip System

- Front adjustable programming functions (Power+ 4, MicroVersaTrip Plus) provide a high degree of flexibility and convenience in making and checking settings.
- Long-time pick up indication is illuminated whenever the breaker is experiencing an overload condition. The light is extinguished by removing the overload or tripping the breaker.
- Glass epoxy printed circuit boards with epoxy conformal coating over all assembled components provide long life with error free operation.
- Switch contacts and board interconnectors provide corrosion resistance and long product life.
- Neutral current sensor connections located between the breaker lugs allow panelboard mounting of breakers without special fillers or increased panel space.
- Fault trip indicators for overload, short circuit, and ground fault are available for local indication.

## Thermal Magnetic and Solid State Trip Types

Spectra RMS $^{\text {TM }}$ circuit breakers with digital rms-sensing electronic trip units provide many features and benefits not offered by thermal magnetic breakers (refer to GET-7002).

Thermal magnetic trip units are available in all GE molded case circuit breakers from $Q$ Line through K frame. Solid state trip units may be alternatively selected for J and K frame circuit breakers. Additionally, non-automatic circuit interrupters, or molded case switches, are available. These interrupters have no automatic overload or short circuit trip elements. They are used for manual switching and isolation.

## Enclosure Compensated Thermal Trip: $40^{\circ} \mathrm{C}$

An enclosure compensated thermal trip is constructed to permit an enclosed circuit breaker in a $25^{\circ} \mathrm{C}$ room ambient to carry $100 \%$ of its nameplate current intermittently and $80 \%$ of its nameplate current continuously when cabled with conductor sized per the UL 489 standard (see Figure 29.1).

The thermal trip action is accomplished by a bimetallic strip. The movement of the bimetal and thus tripping is proportional to the current - high current fast response, low current slow response. This action provides a time delay which prevents service interruptions from normal inrush currents or temporary overloads. Continuous overloads will cause the bimetal to deflect sufficiently to release the latch and open the breaker contacts. However, the bimetal is also sensitive to ambient temperatures. If the room ambient is above or below $25^{\circ} \mathrm{C}$, or the enclosure is warmer than normal, the breaker rating will vary inversely to the temperature: higher ambient-lower current, lower ambient-higher current. Enclosure compensation is furnished on Q-Line, TEB, TEY, TB-1, TED 277 volt and TED 480 volt circuit breakers.

## Ambient Temperature Compensated Thermal Trip: $10^{\circ} \mathbf{T O} 50^{\circ} \mathrm{C}$

An ambient compensating or "Ambient Compensated" thermal trip is the same as an enclosure compensated trip with one notable exception. It has a reduced sensitivity to changes in ambient temperature. In an ambient compensating thermal trip an additional bimetal is added to the circuit breaker. This bimetal responds to breaker ambient and modifies the characteristics of the current sensing bimetal to compensate for ambient temperature changes.

Ambient compensating thermal trips are provided as standard in all 600 volt thermal-magnetic molded case circuit breakers.

## Adjustable Magnetic Trip - F225, J600, K1200 and TEC, TEML, TFC, TJC, TKC, TFL, THLC-2, THLC-4, TLB4

An electromagnet which partially surrounds the bimetal is used to provide instantaneous trip in the event of a short circuit. The high current creates a strong magnetic field attracting the armature and instantaneously releasing the trip latch in the same manner as the bimetal does on overload.

For short circuit protection, the adjustable magnetic trip provides high, low and intermediate trip settings.

## Solid State Trip: - $20^{\circ} \mathbf{~ T O}+55^{\circ} \mathrm{C}$

Solid state MicroVersaTrip ${ }^{\circledR}$ Plus trip units meet the same standards as thermal trip units. Complete circuit breakers equipped with MicroVersaTrip Plus trip units are rated to carry $100 \%$ of their current sensor rating intermittently and $80 \%$ continuously in a $40^{\circ} \mathrm{C}$ breaker ambient. Some MicroVersaTrip Plus equipped breakers are rated to carry $100 \%$ continuously and are so marked.

In addition to the protection of conductors as required by codes and standards, MicroVersaTrip Plus can be set to provide protection for equipment such as motors, generators, or transformers and provide improved distribution system selectivity.

## MicroVersaTrip Plus ${ }^{\text {TM }}$ Tripping Functions

MicroVersaTrip Plus is a trip unit for J and K frame circuit breakers incorporating the newest technological advances in over-current protection for improved reliability, long-life, and flexibility. Operation is fully automatic and normally no external logic or control power inputs are required. It uses digital rms sensing to accurately measure the waveshape and has an LCD display including overload, short circuit, and ground fault indicators.

## Programmable Microelectronic Processor

This forms the basis of the MicroVersaTrip Plus protection programmer. This miniaturization of circuitry provides the increased flexibility required to incorporate nine adjustable time-current functions, three mechanical fault indicators (local), a long-time pickup indicator (local), and zone selective interlocking. All adjustable programmer functions are automatic and self-contained. This compilation of functions provides the basis for the most flexible and useful breaker design presently available anywhere.

## Specially Treated Printed Circuit Boards

Each printed circuit board has a protective conformal epoxy coating to prevent moisture absorption, fungus growth, and signal leakage. All electronics are housed within a metallic enclosure designed to protect against hi-fault interruption arcs, magnetic interference, dust, and other contaminants.

## Flux-Shift Trip Device

A low energy, positive action tripping device which is self-powered by and controlled by the trip unit.

## Current Sensor Package

Three-phase current sensors are incorporated into a single package providing greater flexibility and reliability.

(1) Time delay shown at lower limit of each band. Pick-up tolerances $\pm 10 \%$. Ground fault pick-up not to exceed 1200 amps.
(2) J600 frame with 600-amp sensor for high IC 65kA rating (TJL) limited to 10X.
(3) Pick-up fixed at 1.05C.
(4) Time delay at $600 \%$ of current setting at lower limit of band.
(5) Time delay at $200 \%$ of pick-up setting at lower limit of band.
$X=$ rating plug amps
$S=$ sensor amp rating
C = current setting

## Setup Mode

Set points for all trip unit functions can be entered into the trip system via the 5 -function key pad and LCD display. When working in Setup Mode, the trip unit must be provided with control power from the internal battery, or the MicroVersaTrip Portable Power Pack or by loading the breaker to at least $20 \%$ of its sensor value. While still in Setup Mode, settings can be automatically scanned by depressing the VALUE key for 5 seconds.

## Current Setting (Standard)

The adjustable current setting determines the nominal long time current setting with a $\pm 10 \%$ bandwidth. With a 1.0 setting the breaker will carry indefinitely without tripping the rating plug rating. Changing the setting changes the nominal current rating for the breaker.

## Long-Time Delay (Standard)

This long-time delay adjustment varies the time it will take the breaker to trip under sustained overload conditions. It provides the function of withstanding momentary overloads such as motor starting, welding, or other overcurrent conditions without interrupting the service.

## LShort-Time Pickup (Optional)

This short-time pickup adjustment controls the level of high current the breaker can carry for short periods of time without tripping. Permits downstream breakers to clear short circuit faults without tripping out the upstream protective device.

## Short-Time Delay (Optional)

The short-time delay adjustment is used in conjunction with the short-time pickup setting to provide a further refinement of coordination between circuit breakers. It establishes the time interval the breaker will wait before responding to the short-circuit current level selected on the short-time trip point adjustment.

## Adjustable Instantaneous Pickup (Standard)

The instantaneous trip point determines the level at which the breaker will trip without intentional time delay ( 0.025 seconds or less). This immediate interruption occurs only as a result of a severe overcurrent condition, thereby minimizing damage to the electrical system and equipment.

## Ground Fault Pickup and Ground Fault Delay (Optional)

The ground fault pickup adjustment controls the level of ground fault current at which circuit interruption will occur. To comply with the National Electrical Code (NEC 230-95), no trip point exceeds 1200 amperes. The common square knee of the curve can be replaced with an $I^{2} t$ function to facilitate coordination with downstream devices such as thermal-magnetic breakers and fuses. The ground fault delay adjustment is used to add a pre-determined delay in time to the trip point once the ground fault pickup level has been reached. This provides tripping selectivity between main and feeder or other downstream breakers. The ground fault unit also includes as standard an inverse $I^{2} t$ ramp to substantially improve coordination with downstream protective devices such as fuses and thermal magnetic circuit breakers.

## Memory Circuit

Because of the highly intermittent and erratic nature of arcing ground faults, a memory circuit has been incorporated in all MicroVersaTrip Plus ground fault-sensing circuits as standard. The memory circuit integrates arcing fault current with time, essentially summing the intermittent ground current spikes. In the diagrams, it can be seen how the memory function works.

Diagram A shows a typical ground fault with half-cycles, whole cycles and multiple cycles missing, as normally occurs.

Diagram $B$ shows trip response of a typical ground fault function, which does not include memory. The breaker never trips because the time delay circuits are reset with every missing cycle.

Diagram C shows response of MicroVersaTrip Plus ground fault circuits to the same ground fault; the circuit's memory carries through the missing cycles and generates a trip signal after the preset time delay.

## Status Indication

The LCD display provides continuous information on the operating status of the circuit breaker. Under normal conditions the status screen simply displays the OK message. After a fault event occurs, the LCD display indicates the event type, the magnitude, and overcurrent target when appropriate.

Figure 11.1
Multi-Zone Interlocking

## Zone Selective Interlocking

The standard means of obtaining selectivity between main and feeder breakers is by incorporating programmers with time-coordinated trip characteristics. This consists of setting the farthest downstream breaker with a small time delay, and progressively increasing the time delay as you get closer to the main protective device. The disadvantage of this method is that the system must now endure the stress of a high current fault between the main and feeder until time-out occurs.

The Zone Selective Interlock module, Figure 11.1, receives a signal from a downstream MicroVersaTrip Plus programmer (Logic 0) which causes the module to transmit a low-level interlock signal to a MicroVersaTrip Plus programmer upstream. The interlock signal activates the LED portion of an LED-Transistor Opto-isolator in the upstream programmer causing the fixed delay band to shift from "MIN" to the programmer delay band setting. Both the Short-Time and Ground Fault functions are capable of being interlocked.

Zone Selective Interlocking is available for both the short-time function and the ground fault function, or the ground fault function only.

## Test Jack

The Test Jack located on the front of the rating plug accepts a test cable supplied with a portable, battery operated (or 120Vac) test kit separately available. The test kit will test the circuit breaker while the circuit breaker is carrying load, and provides either a trip or no trip test. The test kit will simulate a time-over current condition for the long-time, short-time and ground fault functions. It will also read trip unit switch settings and provide a report on the trip unit self-test feature.

## Rating Plugs (Standard)

Various rating plugs are available to fix the ampere rating equal to or lower than the sensor ampere rating as in Table 5.2.

## Powert ${ }^{\text {TM }} 4$ Tripping Functions

Power+ 4 is the standard electronic trip device for GE J and K frame circuit breakers. This trip unit is integral to the breaker and is not available separately. Operation is fully automatic and, normally, no external logic or control power inputs are required.

## Protection Trip Unit

The current sensor-powered solid-state logic unit incorporates rotary adjustment knobs for up to four functions. The functions available are Current Setting (standard), Instantaneous Pickup (standard) or Short-time Pickup with Fixed Instantaneous (optional), Ground Fault Delay (optional), and Ground Fault Pick Up (optional). The Long-time Delay features four user selectable bands, and there are three short time constant delay bands with $I^{2} t$ in or $I^{2} t$ out.

## Flux Shift Trip Device

A low energy, positive action tripping device is automatically powered and controlled by the protection programmer.

## Current Sensor Package

Three phase current sensors are incorporated into a single package for maximum flexibility and reliability.

Table 12.1
Power+ 4 Protection Functions and Setting Values

| Protective Function | Pickup Settings | Nominal Midpoint Delay Settings | Delay Curve |
| :---: | :---: | :---: | :---: |

## Current-Limiting Circuit Breakers

## Note: OBSOLETE - for reference use only.

To meet increased demands for electrical service by residential, commercial, and industrial users, and to reduce system power losses and cost, larger low-impedance transformers are being installed by power companies. The result is systems with higher available short circuit currents. Traditional branch circuit equipment cannot handle the fault currents available in these systems which can reach $150,000 \mathrm{rms}$ symmetrical amperes or more.

THLC current-limiting circuit breakers (CLB) react far more quickly to high-level short circuits than conventional breakers. In fact, the higher the short circuit current, the faster the THLC operates, because of its magnetic repulsion design.

Example: if a 150,000 RMS symmetrical ampere short circuit at 480 volts ac were to threaten your system, the THLC1 would interrupt it in just 3 milliseconds. At the same time, the THLC1 would limit peak let-through current to less than 42,000 amperes - only $13 \%$ of the destructive energy that would flow through without THLC1 protection, and a small enough current to be controlled by standard series-connected circuit breakers.

But a fast break isn't enough; a CLB must control arc voltage quickly and efficiently, too.
GE THLC current limiting breakers force the arc into patented, U-shaped arc plates where sufficient voltage is developed to "dominate" the short circuit fast. During a 480 volt interruption, for example, the THLC1 quickly counters the driving voltage with a peak arc-voltage in the range of 800 volts - sufficient voltage to quench the short circuit without causing unwanted dielectric breakdown elsewhere down the line.

And for long, reliable life, the THLC is also equipped with special baffles to vent hot gases out of the breaker during the arc-quenching process.

The THLC current-limiting circuit breaker is designed to protect standard circuit breakers with ratings as low as 10,000 AIC on systems with available currents up to 200,000 RMS symmetrical amps at 240 Vac or at 480 Vac. It's available in amp ratings ranging from 15 to 400 amps .

- UL-listed and CSA certified IC ratings of 200kAIC at 240 and 480 volts and 50kAIC at 600 volts
- Patended arc plates provide fast, efficient control of short-circuit conditions
- Resettable, fuse-free construction minimizes downtime
- Magnetic repulsion contact design interrupts short-circuit currents of up to 200,000 amperes at 480 volts in less than 3 milliseconds - the higher the current, the faster the breaker operates
- Standard circuit breaker protection with ratings as low as $10,000 \mathrm{AIC}$ on systems with available currents up to 200,000 symmetrical rms amperes
- 150-ampere frame size with ampere ratings ranging from 15-150 amperes
- 225-ampere frame size with ampere ratings ranging from 125-225 amperes
- 400-ampere frame size with ampere ratings ranging from 250-400 amperes

## Mag-Break ${ }^{\circledR}$ Motor Circuit Protectors

## Standard Interrupting Devices

Limiter Assisted Devices

Mag-Break motor circuit protectors provides accurate and fast clearing of faults on motor circuits - including low level faults - the type most prevalent in motor installations. Mag-Break serves to minimize damage to motors and motor control apparatus in addition to protecting motor branch circuit conductors. Continuous current ratings and adjustable instantaneous trip ranges have been designed to meet NEC requirements concerning motor full load and locked rotor current. The Mag-Break instantaneous trip point can be set low and precisely (just above asym. motor inrush) assuring fault protection and eliminating nuisance tripping.

Each pole of the Mag-Break motor circuit protector contains a current sensing element to trip the breaker instantaneously when the preselected current setting is exceeded. Mag-Break's unique magnetic system permits independent factory calibration of both the Hi and Lo ends of the trip range. This provides field adjustability with accuracy and repeatability at all Mag-Break trip scale positions.

In addition to the two independent factory calibrations, Mag-Break is field adjustable by screwdriver adjustments on the front of each breaker. The field adjustable setting is continuous over the entire range from Hi to Lo, and each breaker rating label contains a table converting setting position to amperes. An overcurrent on any pole will cause all three poles to trip simultaneously, thus preventing costly single phasing problems.

Table 15.1
Trip Set Positions to Trip Amperes

[^2]
## Accesories

## Undervoltage Protection

The Undervoltage Release instantaneously trips the breaker when voltage drops to $35-70 \%$ of normal rating. The device retrips the breaker if it is closed before normal voltage is restored.

Standard duty and heavy-duty types are available.

Time Delay Unit - for use with UVR. This unit prevents nuisance tripping due to momentary loss of voltage.

A separate, externally mounted unit has 120 volt ac input and 125 volt dc output with delay adjustable from . 1 to .5 seconds. It is used in conjunction with 125 -volt dc undervoltage release, which must be ordered separately.

## Bell Alarm

A bell alarm actuates a warning signal or other circuitry when the breaker is tripped under overload, short circuit, shunt trip, undervoltage trip, and 3 coil shunt trip conditions. Not actuated during normal ON-OFF operation.

## Motor Operator for Remote "On-Off"

A motor-operated mechanism can open, close, or reset a breaker remotely. This convenient attachment mounts integrally with the breaker, without modification to the breaker or its handle. Just lift the cover of the accessory mechanism to operate the breaker manually. Breaker ON-OFF is indicated in the operating mechanism cover.

## Shunt Trip for Remote Tripping

Standard

A Shunt Trip Device can be used to trip and open a breaker by remote control. When the breaker opens, the shunt trip coil circuit is de-energized by means of an auxiliary switch. They meet UL requirements for operation at $55 \%$ of rated voltage for use on ground fault systems.

## Three-coil (Blown Fuse Detector) (not illustrated)

This provides single-phase protection for fused circuit breaker combinations, factory installed only.

It mounts in right pole for TEB, TED, and in left pole for TFK, TJK, TKM. Installed internally similar to standard shunt trip with leads connected across the fuses, it trips the breaker when a fuse blows or if the breaker is closed under load with a fuse open and fits all breaker types including molded case switches. Suitable for system voltages 208 to 600 volts ac.

(1) Left pole mounting not available for 2 pole TEB, TED.
(2) UL listed at 200,000 AIC without internal accessories. 100,000 AIC with internally mounted accessories.
(3) 600 volts AC auxiliary switches are not UL listed.
(4) Formerly green.
(5) Not available with lead exit from the back of breaker.
(6) UL listed interrupting capacity with accessories: 10 K AIC at 600 volts, $A C, 22 \mathrm{~K}$ AIC at 480 volts AC, 22 K AIC at 240 volts $A C$.
(7) Maximum available short circuit application is 85,000 sym rms A.
(8) Accessory mounts in a one-inch frame and increases overall breaker size by one pole added to left side.
(9) Leads are \#18 AWG $125^{\circ} \mathrm{C}$ Vulkene ${ }^{\circledR}$ insulated.
(10) Auxiliary switch is activated in both OFF and tripped positions.

| TFKBAAR | $21 / 2$ amperes, 28 volts ac | GEA-4663 |

## Accessories — Mechanical Data

Mounting Hardware

## Front Connections

Front-connected $\mathrm{Cu}-\mathrm{Al}$ lugs allow easy cable feed. The lug mounts directly to the mounting surface with screws and lockwashers.

## Power Distribution Lugs

Multi-termination lugs enable wiring to multiple devices in UL 508 applications. The lugs are for use on the load side of the breaker only and mount directly to the mounting surface.

## Back Connections

Back-connected studs need to be supported by a sub-base, but make positive contact with each line and load terminal. Studs stay in place while the breaker can be removed or installed.

## Plug-In Mounting

A plug-in base assembly provides for quick changeout of breakers. The assembly backplate mounts to angle-iron cross-pieces. Breaker plug-in terminals align with onepiece backplate assembly.

## Handles and Operating Mechanisms

## TDR Rotary Operating Handle

The Rotary-Operating Integral Handle mounts directly to the breaker, and operates through the door of the enclosure. A mechanical interlock prevents unauthorized opening of the enclosure when the handle is in the ON position. The locking hasp accommodates up to three padlocks. Suitable for horizontally or vertically mounted breakers. Suitable for NEMA 12K and NEMA 12 enclosures when used with gasket kit.

## STDA Flange Handle and Variable Depth Operating Mechanism

The STDA Flange Handle is for use with 150-1200 ampere frame circuit breakers. It is designed to meet automotive duty specifications, and NEMA 12 and NEMA 4/4X. UL recognized components are used. The mechanism is of Quick-Make, Quick-Break type with an integral mounting plate and low operating force. Mounting dimensions fit standard flange enclosures $8^{\prime \prime}-24$ " deep. Detailed installation instructions are provided.

## SCH Cable Operators

Cable operators make it simple to switch circuit breakers mounted in a wide variety of applications. The handle mechanism is combined with one of eight operating cables, ranging in length from 3 to 10 feet, to cover a broad range of possible breaker mounting locations. The breaker operating mechanism mounts directly to the face of the breaker using hardware included with the mechanism. Flange mounted handles are available for NEMA Type $1,3 \mathrm{R}, 12,13$, and 4/4X applications.

## TDM Adjustable Depth Handles

TDM Door-Mounting Handles are available in shallow mounting types and extended shaft type for vertical or horizontal breaker mounting. The mechanism provides interlocking. The door-mounted handle accommodates up to three padlocks. Suitable for NEMA 12K and NEMA 12 enclosures.

NOTE: A pendulum-type handle designated Catalog Number THCH45 is also available for NEMA 4, NEMA 4X, and NEMA 5 enclosures.

# Application Data - Molded Case Circuit Breakers 

Molded case circuit breakers are circuit protective devices that primarily perform two functions: (1) manual switching operation to open and close a circuit by means of a toggle handle and (2) automatic opening of the circuit under sustained overload and/or short circuit conditions. Circuit breakers inherently provide the automatic protective function of opening the circuit under abnormal sustained overload, or short circuit conditions, without the use of fuses. When a circuit breaker opens to clear a fault, the toggle handle goes to a TRIPPED position midway between the ON and OFF positions, thus clearly indicating that a circuit breaker has opened. When the cause of the fault has been removed, the circuit breaker can again be closed simply by moving the toggle handle to the RESET position, and then moving the handle to the ON position.

Circuit breakers have an advantage over fusible elements. A fault on one pole of a multi-pole breaker actuates a common trip bar that opens all poles simultaneously, thus avoiding single phasing a motor circuit, as could occur in a fusible device. Molded case circuit breakers are "trip free" in construction. This means that the circuit breaker contacts cannot be held closed against a fault condition. Molded case circuit breakers are designed to protect insulated conductors against unsafe overheating that would ultimately damage the insulation and conductor.

Thermal-magnetic molded case circuit breakers are not designed to provide motor running overload protection. This function is normally performed by overload relays supplied in manual or magnetic motor starters. However, for infrequently started motors, MicroVersaTrip Plus equipped molded case circuit breakers can be used to provide motor overload, overcurrent, and ground fault protection.

Molded case circuit breakers meet UL Standard 489 covering "Molded Case Circuit Breakers, Molded Case Switches, and Circuit Breaker Enclosures."

UL Standard 489 makes provision for two classes of products - UL Standard rated and UL 100 percent rated. The basis of these ratings for molded case and insulated case circuit breakers is as follows:
A. Standard rated under UL 489

1. Circuit breakers are rated to carry 100 percent of their nameplate current continuously in free air at $25^{\circ} \mathrm{C}$ when cabled per Table 31.1.
2. Enclosed circuit breakers are rated to carry 100 percent of their nameplate current intermittently (up to 3 hours maximum) and 80 percent continuously, with the enclosure in a $25^{\circ} \mathrm{C}$ ambient, and cabled per Table 32.1.
3. Group mounted circuit breakers may require derating of the circuit breaker and cable in room ambient temperatures other than $25^{\circ} \mathrm{C}$ and with cable other than specified in Table 32.1.

## B. 100-percent rated under UL489

1. Circuit breakers are rated to carry 100 percent of their nameplate current continuously in an enclosure with ventilation and volume as specified on the device in a room ambient of $25^{\circ} \mathrm{C}$ when cabled as specified in Table 31.1 using $90^{\circ} \mathrm{C}$ insulation, sized to $75^{\circ} \mathrm{C}$ ampacity.
2. Room ambient temperatures other than $25^{\circ} \mathrm{C}$, cable other than specified in Table 31.1, or enclosure volume and/or ventilation other than specified on the devices may require derating of the system.

(1) Single unit or duplex construction must be specified.
(2) This class may incorporate a current limiting device within the breaker case.
(3) 2-pole rated 480 Vac maximum.
(4) UL/CSA 347Vac maximum.

## Current Ratings

Molded case circuit breakers are designed to protect insulated cable, therefore the characteristics of breakers are closely tied to the Underwriters Laboratories specified size and type of wire for each rating as well as the load characteristics. The following items should be considered when applying and using molded case circuit breakers:
A. Cable size must be equal to or greater than that specified by Underwriters Laboratories Inc. Standard for Safety 489. All GE molded case circuit breakers described in this manual are to be used with $75^{\circ} \mathrm{C}$ ampacity conductors. The use of $90^{\circ} \mathrm{C}$ conductors is acceptable providing they are sized to the $75^{\circ} \mathrm{C}$ ampacities. Using a lug marked "Cu9A1" does NOT make the breaker suitable for use with $90^{\circ} \mathrm{C}$ conductors at $90^{\circ} \mathrm{C}$ ampacity. Thermal current measuring systems (bimetals and fuses) incorporate a resistance element which generates heat at a rate proportional to the square of the current. The cable is used as a heat sink to control the temperature of the bimetal; reducing the size of the conductor raises the temperature and the breaker will carry less current. In general the effect of cable size on breaker thermal calibration is illustrated in Figure 29.1.
B. Ambient temperatures have an even wider effect on the rating of the breaker-cable system. High ambient temperatures not only affect the calibration of the breaker but may cause internal temperatures to exceed the temperature limits of the insulating materials. Cable may be adapted through the use of higher rated materials such as glass or mineral, but this is not possible with switching devices due to mechanical requirements and fabrication techniques. Low temperatures, on the other hand, substantially increase the current carrying ability of the system until other limiting factors occur, such as lubricant failure or binding due to differential contraction of parts. In general the effect of ambient temperature on an ambient compensating breaker calibration looks like Figure 30.1.

Notice that the curve in Figure 30.1 specifies the ambient temperature of the air surrounding the breaker not room temperature. To convert this information to room ambient it is necessary to know the temperature rise of the equipment housing the circuit breaker. This must include factors for group mounting of devices, ventilation, solar insulation, other radiant heat sources, etc. The curve in Figure 30.1 also applies only to devices connected with the UL sized conductor.
C. System operating frequency also has a major effect on the rating and performance of molded case circuit breakers. Most circuit breakers may be directly applied at their published ratings on 50 or 60 Hertz systems, but molded case circuit breakers should not be applied at other frequencies without the concurrence of the General Electric Company except as described on page 36, "Factor C - Frequency Rating".

Two separate effects occur at frequencies above 60 Hertz depending on the method of current sensing. In thermal magnetic devices, the bimetal, which provides overload protection, responds accurately to the applied current. However, the instantaneous element, which is a solenoid constructed of copper and steel, becomes hot. This raises the temperature of the breaker, thereby reducing the continuous current rating of the device. The instantaneous trip solenoid becomes hot because of the nature of its construction and materials. In addition to adding heat to the breaker, the instantaneous trip does not respond to current correctly; the higher the frequency, the less accurate the response.

At nominal system frequencies less than 50 hertz but above direct current, solid-state trip devices become inoperative due to sensor saturation. Thermal trip devices remain accurate while instantaneous trip solenoids lose accuracy. On direct current systems, solid-state trip units are completely inoperative, thermal trip units calibrate accurately, and instantaneous trip solenoids may or may not be accurate depending on the specific construction technique used.

## Figure 29.1

Breaker current rating and conductor size are a matched pair; any insulation type may be used but the cross section must remain constant.

D. Another factor to be considered is the altitude at which the breaker will be applied. The design altitude for molded case circuit breakers is 0 to 6000 feet. At altitudes above 6000 feet the thin atmosphere affects the heat transfer of the breaker as well as its ability to interrupt short circuits. An additional derating of 4 percent is applied at altitudes from 6000 to 10,000 feet.
E. Load type and duty cycle must also be considered in the application of molded case circuit breakers. Loads such as capacitors and electromagnets require a substantial continuous current derating factor if the breaker is normally used to switch the load. Group mounted devices require additional derating due to the lack of free air circulation around the devices.

With loads such as resistance welders, the breaker continuous current rating must be no less than 125 percent of the welder 100 percent duty-cycle rating.

In general, where load protection in addition to cable protection is desired, the load characteristics and protection requirements must be fully evaluated.
F. An additional factor which needs to be considered is a safety factor. If the circuit breaker is run at the current level derived from factors A-E continuously, it will be within its rating and the conductor ratings, but it will be on the verge of tripping, and any perturbation from nominal could cause the circuit breaker to trip. A safety factor of at least 10 percent should be applied to prevent possible nuisance tripping. Other conditions such as excessive load break operations, overload tripping, or severe load cycling can affect breaker life and should be factored into the rating.

The above information is summarized and tabulated on the following pages for your convenience.
The trip time characteristics of GE solid state trip systems which use rating plugs, like MicroVersaTrip® Plus, do not change over ambient temperature variations which are inside the operating temperature range of the trip unit. The operating temperature range for MVT Plus molded case circuit breakers is $-20^{\circ} \mathrm{C}$ to $+55^{\circ} \mathrm{C}$. The operating range for the trip unit is $-20^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$. Accordingly, for breakers with MVT Plus, the items above should be used only for the purposes of determining if a larger frame is required. Rating plugs should be selected based solely on the load current in order to provide the tightest overload protection.

Selecting the rating plug based solely on the actual RMS current also permits use of smaller conductors. Referring to Example \#2 on page 35, it can be seen that if a non-interchangeable trip thermal magnetic breaker had been selected, it would have been rated 400 amperes and (2) $3 / 0$ AWG conductors per phase would have been required (see Table 32.1). Using the solid state trip breaker with interchangeable rating plug, a 300 ampere rating plug would be appropriate for the load and the conductor size is reduced to (1) 350 kcmil .

## Figure 30.1

The effect of ambient temperature on the continuous current carrying ability of the breaker and cable system is shown on page 35, "Factor B - Ambient Temperature."

## Current Rating Selection

Circuit breaker ampere rating $\left(I_{p}\right)=I_{a} \times A \times B \times C \times D \times E \times F \times G$ where:
$I_{a}=$ Actual full-load current or RMS current
$\mathrm{A}=$ Wire size factor
$\mathrm{B}=$ Ambient temperature rating factor
$\mathrm{C}=$ Frequency rating factor
$\mathrm{D}=$ Altitude rating factor
$\mathrm{E}=$ Load class rating factor
F = Safety factor
$\mathrm{G}=1.0$ for intermittent load or 1.25 for continuous load

Table 31.1
Wire and Cable Size by Ampere Rating
Circuit breakers are calibrated and rated for use with the following wire sizes by ampere rating (based on $75^{\circ} \mathrm{C}$ insulation conductor ampacity).

## Selection of Circuit Breaker Current Rating

Circuit breakers are primarily used to provide overload and short circuit protection for insulated conductors. In this regard, the National Electrical Code Article 240-3 (1999 NEC) requires that conductors be protected in accordance with their ampacities, as given in NEC Tables 310-16 or 310-17. Exceptions are listed in the article for certain specific applications or conditions including protection for conductors in motor circuits.

The size and type of conductors required for a given circuit is usually calculated by the consulting engineer or other specifying authority, and specified on the job plans. It is in these instances, relatively simple to select a standard circuit breaker rating that matches the ampacity of the conductor. Where standard circuit breaker ratings do not correspond to the ampacity of the conductor, the NEC allows the next higher rating to be used where rating is 800 amperes or less.

For applications where only load currents are known, and motor circuits, ambient temperature, special duty cycles, frequency and altitude are involved, the following formula for selection of standard circuit breaker ratings is used:

Circuit Breaker Ampere Rating $=$ Actual Load Current $\times A \times B \times C \times D \times E \times F \times G$.
The procedure for using this formula is explained in the following steps.

## Step 1.

Determine the ACTUAL CURRENT of the circuit by adding the continuous load amperes for each load on the circuit. If the load is intermittent, the actual load current is equal to the RMS current over a time period equal to one-tenth of the frame ampere rating in minutes - 100 ampere frame $=10$ minutes, 225 ampere frame -22.5 minutes, etc.

Example \#1:
An air-conditioning compressor cycles on and off at a maximum rate of four per hour and has the following characteristics:

- 62 full load amperes
- 248 locked rotor amperes
- 6 second starting time
- 5 minute off-time between starts

If we use an E frame breaker (150 ampere maximum) we must calculate the RMS current during the worst 10 minute period, which is START and RUN in this example.
$\mathrm{I}_{\text {RMS }}=\frac{\sqrt{(\mathrm{I} \text { start })^{2}(\mathrm{~T} \text { start })+(\mathrm{I} \text { run })^{2}(\mathrm{~T} \text { run })}}{\mathrm{T} \text { total }}=$
$\frac{\sqrt{(248)^{2}(0.1 \text { minute })+(69)^{2}(9.9 \text { minutes })}}{10 \text { minutes }}$
$\mathrm{I}_{\text {RMS }}=66.5$ amperes
If we use an F frame ( 225 amperes) we must calculate the RMS current during the worst 22.5 minute period which is 0.1 minute START, 9.9 minute RUN, 5 minute OFF, 0.1 minute START, 7.4 minute RUN.

$$
\begin{gathered}
\mathrm{I}_{\text {RMS }}=\frac{\sqrt{(248)^{2}(.1)+(62)^{2}(9.9)+(248)^{2}(.1)+(62)^{2}(7.4)}}{22.5} \\
=59.2 \mathrm{amps}
\end{gathered}
$$

## Step 2.

Using the ACTUAL CURRENT, or RMS current determined in Step 1, estimate the breaker frame size required by your application. Retain this "estimated" frame size to complete STEP 3.

## Step 3.

Select the appropriate multiplying factors A to F for the application conditions involved, and substitute in the formula. For applications under the jurisdiction of the National Electrical Code the product of B through G must be equal to or greater than 1.25 for continuous loads on standard rated devices and equal to or greater than 1.0 for 100 percent rated devices.

## Step 4.

Now compute the proper ampere rating and the proper General Electric circuit breaker for the application by multiplying the ACTUAL CURRENT by each of the four factors determined under STEP 3.
Ampere Rating $=$ Actual Current $\times A \times B \times C \times D \times E \times F \times G=$ amperes
Select a breaker having a rating equal to or next above your answer.
Example \#2:
To illustrate: Assume a 480 v three phase load of 260 amperes continuous such as an air-handling fan motor. The available short circuit current is 57 kA . The protective device is individually mounted in a switchboard.

The conductors supplying the load will be selected to be equal to 1.25 times the load current.
Ambient temperatures inside the box will not exceed $40^{\circ} \mathrm{C}$.
A solid state breaker with a rating plug and long time, short time, ground fault and instantaneous protection is required.

There are no appreciable harmonics associated with the load and the instantaneous inrush is 7.8 times motor full load amperes.

The mounting location will be at 7200 ft .
Circuit Breaker Ampere Rating $=I$ continuous $\times A \times B \times C \times D \times E \times F \times G$.
Rating $=260 \times 1.0 \times 1.0 \times 1.0 \times 1.04 \times 1.0 \times 1.1 \times 1.25=371.8$ amperes.
Select a 400A frame MicroVersaTrip® Plus, TJL4S with a C204LSIG programmer. Since the rating plug is not affected by load characteristics other than the actual RMS current value, select a 300 A rating plug rather than a 400A plug.

## Interrupting Ratings

Circuit breakers must not only carry the circuit current at all times under normal conditions and trip open under overload conditions, but must have sufficient interrupting capacity to successfully interrupt short circuit current that will flow under the worst fault conditions that can occur.

## Basis of Interrupting Ratings

## Short-Circuit Current

Interrupting ratings depend upon knowing the magnitude of the short-circuit current that may flow through the circuit breaker or molded case switch. Devices rated in accordance with UL Standard 489 list their interrupting rating in terms of rms symmetrical amps.

The procedures for calculating short-circuit current and the $X / R$ ratios are described in detail in GE Publication GET-3550.

Generally, electrical power system engineers calculate the $\mathrm{X} / \mathrm{R}$ ratios rather than the power factors of protected circuits during their short-circuit studies. The magnitude of the momentary peak current to be interrupted - or withstood is a function of the maximum peak current displacement from the zero current axis. That displacement is a function of the $\mathrm{X} / \mathrm{R}$ ratio (or power factor) of the faulted circuit. The higher the $\mathrm{X} / \mathrm{R}$ ratio, the lower the power factor, and the greater the magnitude of peak current displacement.

Listed interrupting ratings (Table 38.1) are subject to derating where circuit power factors are below listed values. Table 39.2 lists rating factors versus $\mathrm{X} / \mathrm{R}$ ratios and power factors to allow the user to compensate the interrupting rating of a circuit breaker for circuit power factor, where necessary.

## Frequency

Frequency has an effect upon the interrupting capability of a molded case circuit breaker. Exhaustive testing has been conducted at the two worldwide standard frequencies, 50 Hz and 60 Hz . Less testing has been conducted on industrial circuit breakers at 25 Hz and 400 Hz . Table 40.1 lists suggested application guidelines for circuit breakers in 400 Hz circuits.

The data shown takes into account the lack of world test facilities to verify 400 Hz performance, but does represent the existing best engineering judgment of General Electric.

## Power Factor or X/R Ratio

Interrupting ratings of molded case circuit breakers are based upon a specific ratio of reactance-to-resistance, or a specific power factor. Since practical ac circuits contain some reactance, there is some displacement between current and voltage waveforms. Because a short-circuit can literally occur during any point of the voltage wave, an actual trace of short-circuit current may display considerable initial displacement from zero axis.

Figure 36.1
Symmetrical Ac Waveform

Figure 36.1 shows a symmetrical ac current waveform that would occur if a purely resistive circuit was short-circuited (or even a circuit containing reactance if the short circuit occurred at precisely the right point in the voltage waveform - which is unlikely).

Figure 37.1 shows the current trace of a short circuited ac circuit where displacement about the zero axis exists as a consequence of when the short circuit is applied and the amount of reactance in the short-circuited circuit, compared to its resistance.

Figure 37.1
Asymmetrical Ac Waveform

## Interrupting Ratings

There is a simple relationship between the power factor of a short-circuited circuit and its $\mathrm{X} / \mathrm{R}$ ratio. It is:

Power Factor (in Percent) $=\frac{\mathrm{R}}{\mathrm{Z}} \times 100$
and: $\mathrm{Z}=\sqrt{\mathrm{R}^{2}+\mathrm{X}^{2}}$
therefore $\mathrm{PF}=\frac{\mathrm{R}}{\sqrt{\mathrm{R}^{2}+\mathrm{X}^{2}}} \times 100$

R = Circuit Resistance
X = Circuit Reactance
$\mathrm{Z}=$ Circuit Impedance
nterrupting ratings not UL listed are based on tests per NEMA Standard AB-1 "Molded Case Circuit Breakers." The basic rating is given in RMS symmetrical amperes, the preferred basis for selection and application.

In dc applications, values of UL listed interrupting ratings are maximum amperes.

(1) Includes $J, K, C$, and $4 V$ suffixes.
(2) Includes $C, M A$ and $4 V$ suffixes.
(3) Includes $4 V$ suffixes.
(4) Interchangeable thermal-magnetic trip circuit breakers are not UL listed for reverse feed.
(5) Single pole limit.
(6) If model is rated for 600 volts.
(7) 110A for THOC.

Note: The single pole interrupting ratings shown are the UL listed values for three pole devices and are not necessarily the maximum capability of the device. Single pole interrupting capability must be considered when molded case circuit breakers are used on ungrounded or resistance grounded distribution systems.
Note: For series-connected ratings with main circuit breakers or fuses, refer to publication DET-008.

* Not UL listed.
(1) UL listed for 500 volts 3 poles in series ungrounded battery applications.

Notes:

1. Direct current interrupting ratings are based on a system fault time constant of 8 ms (milliseconds) or less.
2. Multi-pole ratings (2 or 3) are based on midpoint grounded systems with one pole in positive leg and one pole in negative leg, or end grounded systems with two or three poles wired in series in the ungrounded leg.
3. Single-pole ratings are for application in ungrounded systems.

(1) Includes soild state trips.

Note: 400-Hertz interrupting ratings are based on engineering judgement, taking into consideration the operating characteristics of molded case circuit breakers and the worldwide lack of test facilities to verify performance.

Table 40.2
O-Line and TEB Molded Case Switch Short Circuit Withstand Rating(1)

| Molded Case Switch <br> Catalog Number | Maximum Rating <br> Protective Device ${ }^{2}$ |  | Short Circuit <br> Withstand Rating |
| :---: | :---: | :---: | :---: |
|  | Voltage | Amps | Amps rms Sym |
| TOL, TQB, TQC21Y690 | $120 / 240$ | 60 | 10,000 |
| TOL, TQB, TQC21Y100 | $120 / 240$ | 100 | 10,000 |
| TQL, TQB, TQC22Y60 | 240 | 60 | 10,000 |
| TQL, TQB, TQC22Y100 | 240 | 100 | 10,000 |
| TQL, TQB, TQC32Y60 | 240 | 60 | 10,000 |
| TQL, TQB, TQC32Y100 | 240 | 100 | 10,000 |
| TEB111Y100 | 240 | 100 | 10,000 |
| TEB122Y100 | 240 | 100 | 10,000 |
| TEB132Y100 | 240 | 100 | 10,000 |

(1) Q-Line and TEB molded case switches have a 10,000 amp symmetrical short circuit withstand rating when protected by a fuse or circuit breaker rated 10,000 amps IC or greater and whose ampere rating does not exceed the ampere rating of the switch.
(2) Protective device must be on line side of molded case switch.

Note: Circuit breakers, Mag-Break ${ }^{\circledR}$ instantaneous only breakers and molded case switches are inherently horsepower rated by the testing performance requirements in UL489. They are therefore not marked with horsepower ratings. See NEC Article 430-109.

[^0]:    (1) For single-phase, 3-wire or 3-phase, 4-wire applications, select appropriate neutral current sensor.
    (2) TJL4V with 500A and 600A sensors available with adjustable instantaneous only.

[^1]:    (1) Consult published trip-time curves for tolerances.
    (2) Obsolete type.

[^2]:    (1) For motors above 350 Hp use Power+ 4 or MicroVersaTrip Plus equipped breakers.
    (2) Tolerance $\pm 20 \%$ of nominal value.

[^3]:    (1) The correct size wire should be used with every circuit breaker. The values shown above can be useful in understanding the response of the breaker in some misapplications or in applications where cable ampacity is not required to match breaker ampacity.

[^4]:    (1) Equals the product of the load class rating factors which apply to the circuit in question.
    (2) Refer to the NEC Article 430, Part B, for conductor and circuit breaker sizing.

[^5]:    (1) $\mathrm{kA}=$ Kiloamps ( 1 kA is $1,000 \mathrm{amps}$ ) rms, symmetrical.
